Introduction

Technical excellence during the fabrication of the prosthesis and effective management of patient are the two important features for a successful complete denture therapy. Even the most accomplished practitioners find difficulty in satisfying the patient’s expectations for stability and retention of the denture and it is often considered appropriate to prescribe a denture adhesive for these patients. Denture adhesives may also give psychological confidence for the patient as it supplements retention and stability especially during occasions of public interaction. However, denture adhesives should not be used as a method to improve retention in an improperly fabricated ill-fitting denture, and under any circumstances excessive amounts of denture adhesive should be indicated. Standardized guidelines are needed for the application, use and removal of denture adhesives.

Though the usage of denture adhesives dates back to the late 18th century, the first mention of adhesives in literature was only in the 19th century. Denture adhesives were initially formulated by mixing vegetable. The mucilaginous substratum formed when they absorbed saliva stuck to the tissues and to the prosthesis.

Kapur’s study in 1967 on 26 denture wearers, highlighted that concomitant use of denture adhesives added to the retention and improved denture wearers’ incisive ability.

Figueiral et al. evaluated the retentive effect of different denture adhesives on maxillary complete dentures using an intraoral transducer and demonstrated retention of complete maxillary dentures were improved with the use of denture adhesives. The denture adhesives improved denture retention and stability and found that patients perceived improved confidence and comfort, better stability, and retention and decreased accumulation of food particles beneath the denture.

Coates studied about the incidence of usage of denture adhesive and found that only 6.9% used denture adhesive on a regular basis. The effectiveness of denture adhesive in improving the stability and retention of the maxillary complete denture were determined in vivo by Chew et al. using Kinseography.

Panagiotouni et al. in their studies found that denture adhesive materials showed a greater retentive ability compared to saliva, and when the adhesives were used in combination with artificial saliva their retentive ability was found to be significantly increased. Chowdhry et al. in their studies found that the paste form of adhesive materials is more resistant to dislodgement compared to the powder form. Abdelmelak and Michael in their studies demonstrated that the cushioning effect of denture adhesives reduced the pressure and friction transmitted to the underlying mucosa.

Composition

The main ingredients of denture adhesives are classified into three groups.

Group 1 (Adhesive agents)

Tragacanth, gelatin, methyl-cellulose, acacia, hydroxyethyl-methyl cellulose, Karaya gum, sodium carboxyl-methyl cellulose, pectin, and synthetic polymers like acrylamides, acetic, polyvinyl and polyethylene oxide.

Group 2 (Anti-microbial agents)

Sodium tetraborate, ethanol, hexachlorophene, and sodium borate.
**Group 3 (Other agents)**
Plasticizing agents, flavoring agents like oil of peppermint, oil of wintergreen, and wetting agents, etc.

**Mode of Action**
Denture adhesives are supplied as a paste, powder or cream.

As the Adhesive powders absorb water, they swell to many times their original volume and the anions so formed, interact with cations in the proteins in the oral mucous membrane. The viscosity of the adhesive is increased by the thick saliva formed, thereby increasing the denture retention.

Newer adhesive materials provide stronger bio-adhesive and cohesive forces. Free carboxyl groups formed by the hydration of adhesive such as methyl cellulose, hydroxyl methyl cellulose, sodium carboxyl-methyl cellulose or poly methyl vinyl-ether maleic anhydride, etc. form electrovalent bonds that produce stickiness or bio adhesion.

The increased viscosity of the adhesive creams results in their lateral spread excluding air and saliva thereby increasing the retention.

**Requirements of an Ideal Denture Adhesive**

1. Available as gels, creams, and powders.
2. Biocompatible, nontoxic and non-irritant.
3. It should have a neutral odor and taste.
4. Easy application and removal from the tissue surface of the denture.
5. Discourage microbial growth.
6. Adhesiveness should be retained for 12-16 h.
7. Increase the comfort, retention and stability of the denture.

**Mode of Application**
Any residual adhesive should be removed from the tissue-bearing surface of the denture.

1. Food debris on the tissue surfaces of the denture is wiped clean.
2. Wet dentures before application of adhesive.
3. Small amounts of adhesive are applied to the tissue-bearing surface of the denture.

• In the maxillary denture – anterior alveolar ridge, the center of the hard palate and posterior palatal seal region.

• In the mandibular denture – adhesive must be applied along the entire sulcus.

4. Denture should be seated and held in place firmly by hand pressure for 5-10 s.
   • Gauze is used to remove excess adhesive.
   • Patient is advised to close into centric occlusion several times to spread the adhesive as a thin even layer.

**Indications**
1. Recording jaw relations and denture try in should be done using stable and retentive bases. Denture adhesives stabilize the trial denture bases which show inadequate retention and stability due to various reasons.
2. Use of adhesives will increase denture try-in accuracy and decrease the patient apprehension about the fit of the final prosthesis.
3. Use of adhesives in patients with compromised denture bearing areas adds to their confidence thereby increasing the ability to adapt to the new prosthesis.
4. Immediate denture gets loosened soon due to tissue healing and resorption requiring relining, rebasing, or a new denture fabrication. Comfort and function during the interim period are aided by the use of a denture adhesive.
5. Reduced clinical findings of ulcers, tissue irritation, inflammation and compression of the oral mucosa of denture wearers were seen with concomitant use of adhesives.
6. Xerostomia in denture wearers either drug or radiotherapy induced can be alleviated with the use of denture adhesives.
7. Stabilization of dentures in patients with hormonal changes and neuromuscular disorders such as myasthenia gravis, Parkinson’s and Alzheimer’s disease, etc., can be achieved with denture adhesives.
8. Prosthesis to rehabilitate gross maxillofacial defects requires denture adhesives for retention.
9. Denture adhesives are valuable adjuncts to the retention of radiation carriers or radiation protection prostheses.
10. Usage of minimal amounts of adhesives provides high profile patients like attorneys, executives, speakers, etc. with psychological security in social situations.

**Contraindications**
1. Allergies to denture adhesives or any of its components.
2. Gross inadequacies in retention and function.
3. Excessive bone resorption and soft tissue shrinkage leading to loss of vertical dimension.
4. Adhesives should not be used to retain fractured dentures or dentures with lost flanges.
5. Patients with inability to maintain proper hygiene of the denture should avoid the use of denture adhesive.

**Conclusion**
With proper use denture adhesives are beneficial to the patient in increasing retention and stability, enhanced comfort, improved function, and in providing psychological satisfaction. They should not be used as an aid to compensate for denture deficiencies even though adhesives enhance denture performance. Patients should not use denture adhesives inadvertently without proper guidance and instructions from the dentists.
